## Analysys Tsp\_filtered\_DPsiP

Each half wave is analysed:

- **Amplitude** exceeds allowable threshold?
- **Amplitude** decreases too much?
- Is half wave length in the permitted range ? ( $\Rightarrow$  Frequency  $\sim 0.5$  to  $1.5$  Hz)
- Does half wave length change too much ?

Fig. 2

3/5

Fig. 3

a) Snaking of car-trailer combination; Oscillation without corresponding steering angle variation

----- yaw rate  
 - - - - steering angle  
 ——— difference between measured yaw rate and model yaw rate

b) Slalom maneuver; oscillation is produced by steering angle variation alone; difference equals zero because vehicle is able to follow the model

c) Slalom maneuver (dynamic); oscillation is produced by steering angle variation alone; difference equals zero because vehicle is no longer able to follow the model

Filtered model yaw rate deviation

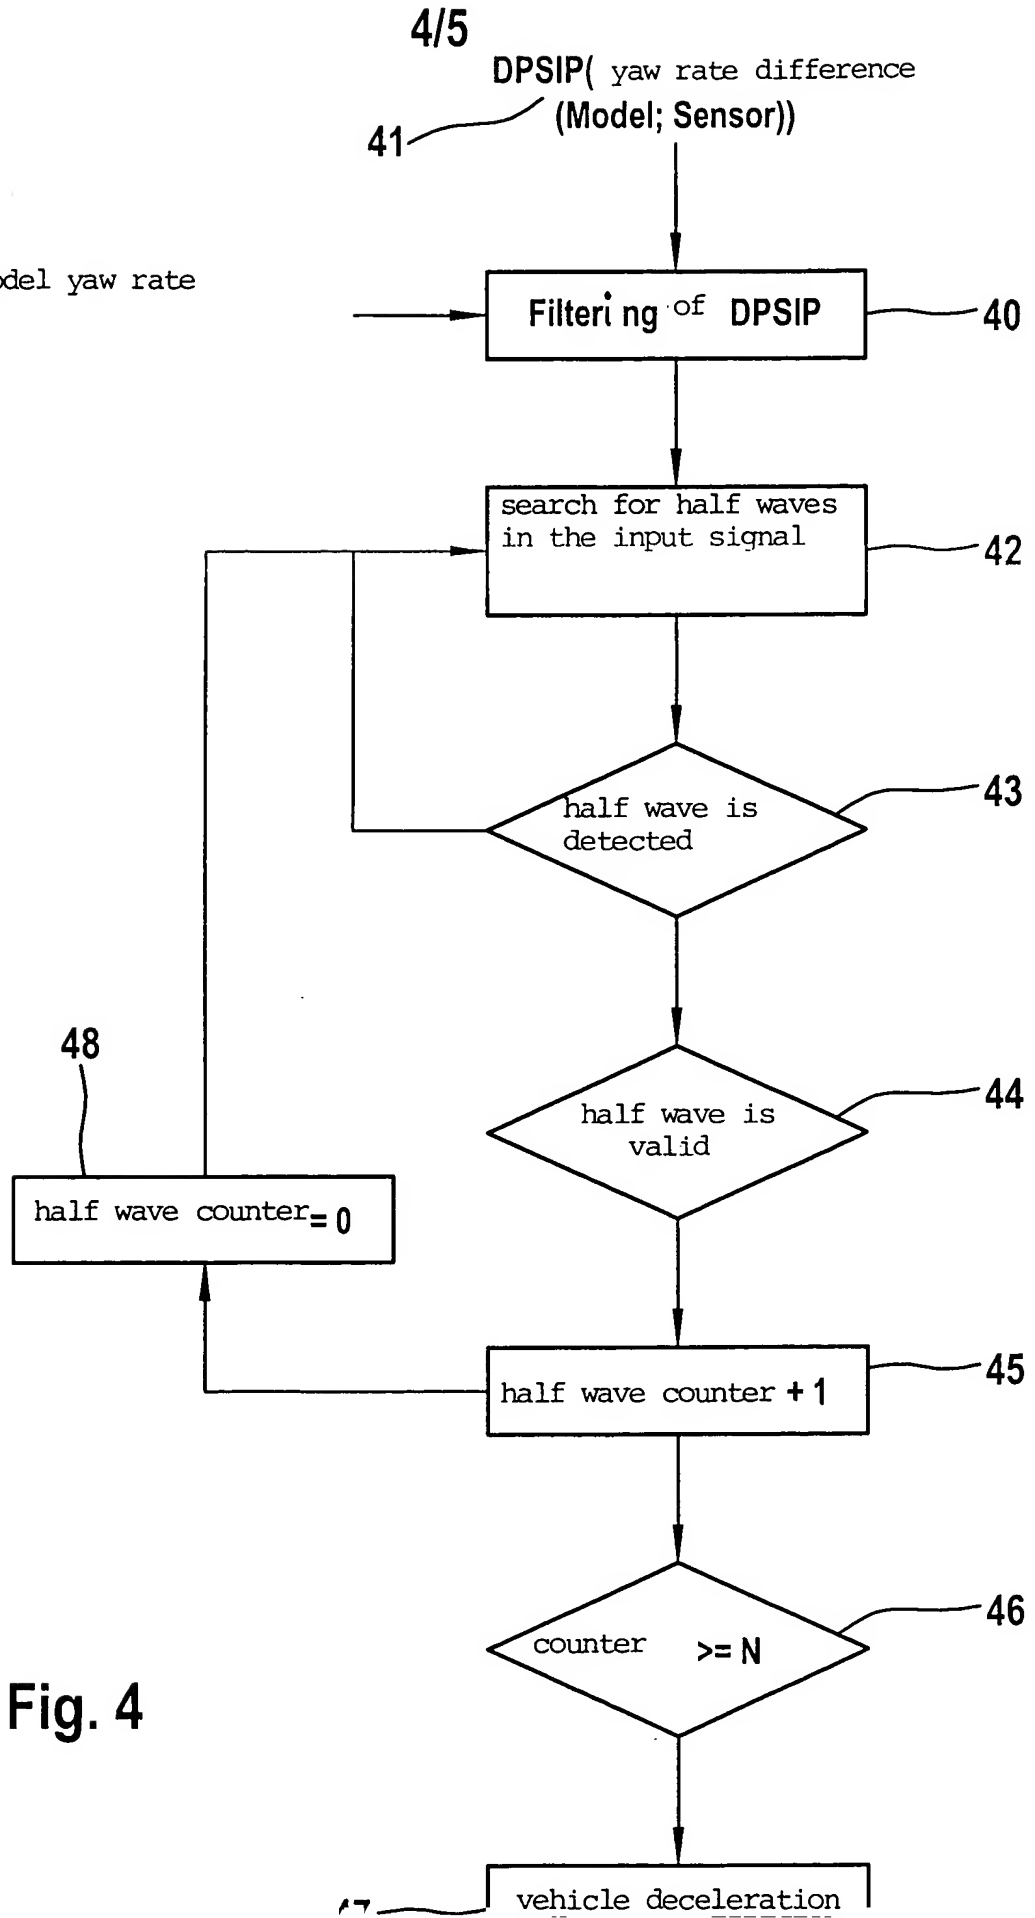

Fig. 4

# Calculation of Tsp\_filtered\_DPsiP

5/5

• Deviation is calculated from the measured yaw rate and the model yaw rate.

• Spurious detection is prevented at high steering dynamics.

• Irrelevant frequency components ( $\sim 1.5\text{Hz}$ ) are filtered out.

$Tsp\_filtered\_DPsiP$  is the main detection signal.

\*  $DPsiP: \Delta d\Psi/dt$
